### KNN Workbook for CS145 Homework 3

\*\*PRINT YOUR NAME AND UID HERE!\*\*

NAME: Wu, Michael UID: 404751542

Please follow the notebook linearly to implement k-nearest neighbors.

Please print out the workbook entirely when completed.

The goal of this workbook is to give you experience with the data, training and evaluating a simple classifier, k-fold cross validation, and as a Python refresher.

### Import the appropriate libraries

```
In [1]: import numpy as np # for doing most of our calculations
import matplotlib.pyplot as plt# for plotting
from cs145.data_utils import load_CIFAR10 # function to load the CIFAR-10 data
set.

# Load matplotlib images inline
%matplotlib inline

# These are important for reloading any code you write in external .py files.
# see http://stackoverflow.com/questions/1907993/autoreload-of-modules-in-ipyt
hon
%load_ext autoreload
%autoreload 2
```

```
In [2]: # Set the path to the CIFAR-10 data
    cifar10_dir = './cs145/datasets/cifar-10-batches-py'
    X_train, y_train, X_test, y_test = load_CIFAR10(cifar10_dir)

# As a sanity check, we print out the size of the training and test data.
    print('Training data shape: ', X_train.shape)
    print('Training labels shape: ', y_train.shape)
    print('Test data shape: ', X_test.shape)
    print('Test labels shape: ', y_test.shape)
Training data shape: (50000, 32, 32, 3)
```

Training labels shape: (50000,)
Test data shape: (10000, 32, 32, 3)
Test labels shape: (10000,)

I like CS 145.

```
y = \sigma(X) + 1
```

```
In [3]: # Visualize some examples from the dataset.
        # We show a few examples of training images from each class.
        classes = ['plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'shi
        p', 'truck']
        num_classes = len(classes)
        samples_per_class = 7
        for y, cls in enumerate(classes):
            idxs = np.flatnonzero(y_train == y)
            idxs = np.random.choice(idxs, samples_per_class, replace=False)
            for i, idx in enumerate(idxs):
                plt_idx = i * num_classes + y + 1
                plt.subplot(samples_per_class, num_classes, plt_idx)
                 plt.imshow(X_train[idx].astype('uint8'))
                plt.axis('off')
                if i == 0:
                     plt.title(cls)
        plt.show()
```

```
In [4]: # Subsample the data for more efficient code execution in this exercise
    num_training = 5000
    mask = list(range(num_training))
    X_train = X_train[mask]
    y_train = y_train[mask]

    num_test = 500
    mask = list(range(num_test))
    X_test = X_test[mask]
    y_test = y_test[mask]

# Reshape the image data into rows
    X_train = np.reshape(X_train, (X_train.shape[0], -1))
    X_test = np.reshape(X_test, (X_test.shape[0], -1))
    print(X_train.shape, X_test.shape)

(5000, 3072) (500, 3072)
```

# K-nearest neighbors

In the following cells, you will build a KNN classifier and choose hyperparameters via k-fold cross-validation.

```
In [5]: # Import the KNN class
    from lib import KNN

In [6]: # Declare an instance of the knn class.
    knn = KNN()

# Train the classifier.
    # We have implemented the training of the KNN classifier.
    # Look at the train function in the KNN class to see what this does.
    knn.train(X=X_train, y=y_train)
```

#### **Questions**

- (1) Describe what is going on in the function knn.train().
- (2) What are the pros and cons of this training step of KNN?

#### **Answers**

- (1) The classifier simply stores the training data.
- (2) This is O(1) time so it is very fast. Unfortunately, a con is that the calculations take place during prediction, so prediction is slow. This is in comparison to something such as a linear classifier that trains slower but predicts very fast.

### **KNN** prediction

In the following sections, you will implement the functions to calculate the distances of test points to training points, and from this information, predict the class of the KNN.

```
In [7]: # Implement the function compute_distances() in the KNN class.
# Do not worry about the input 'norm' for now; use the default definition of t
he norm
# in the code, which is the 2-norm.
# You should only have to fill out the clearly marked sections.

import time
time_start =time.time()

dists_L2 = knn.compute_distances(X=X_test)

print('Time to run code: {}'.format(time.time()-time_start))
print('Frobenius norm of L2 distances: {}'.format(np.linalg.norm(dists_L2, 'fro')))
```

Time to run code: 35.53952741622925

Frobenius norm of L2 distances: 7906696.077040902

### Really slow code

Note: This probably took a while. This is because we use two for loops. We could increase the speed via vectorization, removing the for loops. Normally it may takes 20-40 seconds.

If you implemented this correctly, evaluating np.linalg.norm(dists\_L2, 'fro') should return: ~7906696

#### KNN vectorization

The above code took far too long to run. If we wanted to optimize hyperparameters, it would be time-expensive. Thus, we will speed up the code by vectorizing it, removing the for loops.

```
In [8]: # Implement the function compute_L2_distances_vectorized() in the KNN class.
# In this function, you ought to achieve the same L2 distance but WITHOUT any
for loops.
# Note, this is SPECIFIC for the L2 norm.

time_start =time.time()
dists_L2_vectorized = knn.compute_L2_distances_vectorized(X=X_test)
print('Time to run code: {}'.format(time.time()-time_start))
print('Difference in L2 distances between your KNN implementations (should be
0): {}'.format(np.linalg.norm(dists_L2 - dists_L2_vectorized, 'fro')))

Time to run code: 0.3987753391265869
Difference in L2 distances between your KNN implementations (should be 0): 0.
0
```

### Speedup

Depending on your computer speed, you should see a 20-100x speed up from vectorization and no difference in L2 distances between two implementations.

On our computer, the vectorized form took 0.20 seconds while the naive implementation took 26.88 seconds.

## Implementing the prediction

Now that we have functions to calculate the distances from a test point to given training points, we now implement the function that will predict the test point labels.

```
In [9]: # Implement the function predict_labels in the KNN class.
# Calculate the training error (num_incorrect / total_samples)
# from running knn.predict_labels with k=1

error = 0
y_pred = knn.predict_labels(dists_L2)
for i in range(y_pred.size):
    error += (y_pred[i]!=y_test[i])
error /= y_pred.size

print(error)

0.726
```

If you implemented this correctly, the error should be: 0.726. This means that the k-nearest neighbors classifier is right 27.4% of the time, which is not great.

#### **Questions:**

What could you do to improve the accuracy of the k-nearest neighbor classifier you just implemented? Write down your answer in less than 20 words.

#### **Answers:**

Increase the number of nearest neighbors to look at. This is a tuning parameter and needs to be tested.

### The End of KNN Workbook

Please export this workbook as PDF file (see instructions) after completion.
